

Git

A distributed version control system

Git

Git – versijų kontrolės sistema sukurta dar 2006 ir itin išpopuliarėjusi web kūrimo scenoje. Šiuo metu ji turi daug naudingų funkcijų, aktyvią kūrėjų komandą, didelę publiką ir ne vieną nemokamą hostingo tiekėją.

Diegimas

Git kūrėjai diegimo paketus pateikia *Mac OS X*, *Windows*, *Linux* ir *Solaris OS*. Visus juos galima atsisiųsti iš oficialaus *Git* puslapio. Čia pateiksiu *Windows* diegimo instrukcijas.

1. Atsisiunčiame ir paleidžiame diegimo paketą.
2. Lange „*Adjusting your PATH environment*“ pasirenkame „*Use Git Bash only*“.
3. Lange „*Choosing the SSH executable*“ pasirenkame „*Use OpenSSH*“.
4. Paskutiniame lange renkamės „*Checkout Windows-style*“ ir „*commit Unix-style line endings*“ ir pradedame diegimą.

Diegimui pasibaigus darbalaukyje atsiras *Git Bash* aplikacija, kurią ir naudosime dirbdami su *Git*.

Nustatymai

Visų pirma patartina nusistatyti vartotojo informaciją. Kiekvieną kartą perkeliant pakeitimus į istoriją bus pateikiamas vartotojo vardas ir el. paštas. Atsidarome *Git Bash* ir įvedame:

```
git config --global user.name "Vardas"
```

```
git config --global user.email vardas@elpastas.lt
```

Šios eilutės išsaugos jūsų vardą ir el. pašta, kuriuos naudos kiekvienai naujai saugyklai. Norint pakeisti duomenis konkrečiai saugyklai, jos direktorijoje vykdome tas pačias komandas tik be parametro *–global*.

Saugyklos sukūrimas

Skirtumas tarp *Git* saugyklos ir paprasto projekto – *.git* aplankas pagrindinėje direktorijoje. Norint paversti projekto aplanką *Git* saugyklą tereikia įvykdyti paprastą komandą:

```
git init kelias_link_reikiamo_aplanko
```

Nenurodžius kelio saugykla bus sukurta esamoje direktorijoje.

Saugyklos klonavimas

Taip pat galima klonuoti jau egzistuojančią saugyklą:

```
git clone
```

```
ssh://user@host/kelias/iki/saugyklos.git
```

```
kelias/iki/klonavimo/aplanko
```

Neįrašius kelio iki aplanko saugykla bus nukopijuota į esamą direktoriją. Nurodžius neegzistuojantį aplanką – jis bus sukurtas. Prisijungimui taip pat galima naudoti tokius formatus:

- `git://host.xz[:port]/kelias/iki/saugyklos.git/`
- `http[s]://host.xz[:port]/kelias/iki/saugyklos.git/`

Saugyklos pokyčiai

Prieš dalinantis pakeitimais su kitais vartotojais reikia pažymėti, kuriuos pakeitimus norime perkelti. Taip galima dirbti prie kelių skirtingų projekto aspektų vienu metu ir dalintis tik pabaigtais failais. Norėdami pridėti failą vykdome šią komandą:

```
git add failo_pavadinimas
```

Norint pridėti visus failus, kuriuose buvo atlikti pakeitimai, tiesiog vietoj failo pavadinimo įrašome tašką.

O norėdami ištrinti failą iš saugyklos istorijos vykdome šią eilutę:

```
git rm --cached failo_pavadinimas
```

Ši komanda failą pašalins tik iš saugyklos istorijos, bet iš saugyklos jo neištrins!

Taip pat galima peržiūrėti failus, kurie šiuo metu yra pridėti ar ištrinti:

```
git status
```

Dar viena naudinga komanda:

```
git diff
```

Ji pateikia visus pakeitimus, kurie buvo atlikti, bet dar neperkelti nei į saugyklos istoriją, nei į projekto istoriją. Norint pamatyti visus pakeitimus, kurie yra perkelti į saugyklos istoriją tereikia pridėti parametrą *–cached* komandos pabaigoje.

Projekto pokyčiai

Perkėlus visus norimus pakeitimus į saugyklos istoriją, galima judėti link projekto istorijos. Norint perkelti pakeitimus į projekto istoriją reikia sukurti pakeitimų įrašą. Įrašė yra išsaugoma vartotojo informacija, žinutė apie pakeitimus kitiems vartotojams ir unikalūs ID. Norint sukurti įrašą projekto istorijoje, vykdome šią komandą:

```
git commit -m "Žinute apie pakeitimus"
```

O šią komandą vykdome norėdami peržiūrėti projekto pakeitimų istoriją:

```
git log
```

Pokyčių anuliavimas

Git turi ne vieną pakeitimų stadiją, todėl ir pokyčių anuliavimas gali būti įvairus. Anuliuoti pokyčius galima jų dar neperkėlus į projekto istoriją šiomis komandomis:

```
git reset --hard HEAD
```

```
git clean -f
```

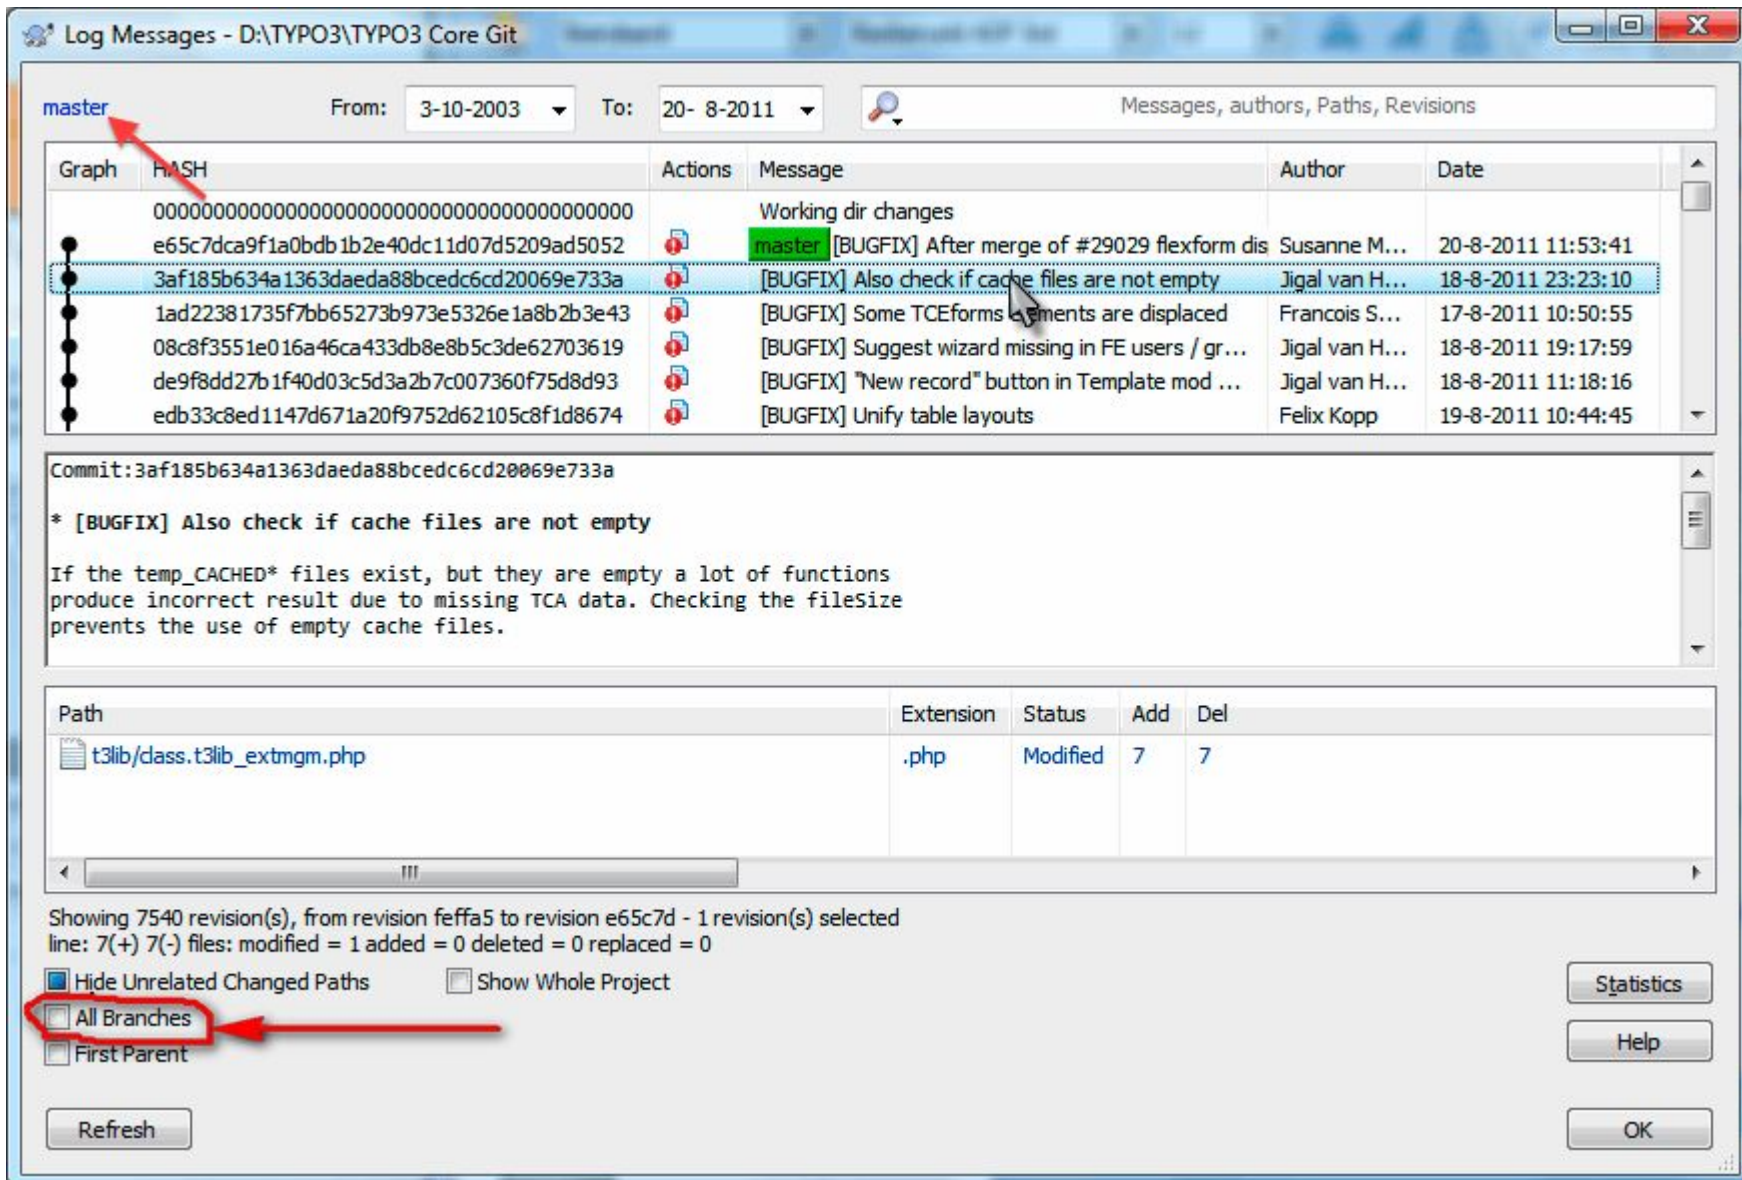

Komanda *reset* grąžina saugyklą ir jos istoriją į padėtį, kuri buvo aprašyta paskutiniame projekto įrašė. Komanda *clean* ištrina visus pakeitimus failuose, kurių nebuvo projekto istorijoje.

Taip pat galima anuliuoti pakeitimus konkrečiame faile:

```
git checkout HEAD failo_pavadinimas
```

Komanda pakeis failą į naujausią jo versiją projekto istorijoje.

<https://tortoisegit.org/>

Komandos

`git clone https://sssss/sss.ss.git`

`git init`

`git status`

`git add .`

`git commit -m "message what was done"`

`git push`

`git pull origin master`

`git merge mindaugo_branchas`

Bandom

git clone <https://github.com/Mxas/debts.git>

git clone <https://github.com/kolorobot/spring-boot-thymeleaf.git>

git clone <https://github.com/shopizer-ecommerce/shopizer.git>

git clone <https://karpinskas@bitbucket.org/karpinskas/mokykla.git>

EN

Version control systems

- **Version control** (or **revision control**, or **source control**) is all about managing multiple versions of documents, programs, web sites, etc.
 - Almost all “real” projects use some kind of version control
 - Essential for team projects, but also very useful for individual projects
- Some well-known version control systems are CVS, Subversion, Mercurial, and Git
 - CVS and Subversion use a “central” repository; users “check out” files, work on them, and “check them in”
 - Mercurial and Git treat all repositories as equal
- Distributed systems like Mercurial and Git are newer and are gradually replacing centralized systems like CVS and Subversion

Why version control?

- For working by yourself:
 - Gives you a “time machine” for going back to earlier versions
 - Gives you great support for different versions (standalone, web app, etc.) of the same basic project
- For working with others:
 - Greatly simplifies concurrent work, merging changes
- For getting an internship or job:
 - Any company with a clue uses some kind of version control
 - Companies without a clue are bad places to work

Why Git?

- Git has many advantages over earlier systems such as CVS and Subversion
 - More efficient, better workflow, etc.
 - See the literature for an extensive list of reasons
 - Of course, there are always those who disagree
- Best competitor: Mercurial
 - I like Mercurial better
 - Same concepts, slightly simpler to use
 - In my (very limited) experience, the Eclipse plugin is easier to install and use
 - Much less popular than Git

Download and install Git

- There are online materials that are better than any that I could provide
- Here's the standard one:
<http://git-scm.com/downloads>
- Here's one from StackExchange:
<http://stackoverflow.com/questions/315911/git-for-beginners-the-definitive-practical-guide#323764>
- Note: Git is primarily a command-line tool
- I prefer GUIs over command-line tools, but...
- The GIT GUIs are more trouble than they are worth (YMMV)

Introduce yourself to Git

- Enter these lines (with appropriate changes):
 - `git config --global user.name "John Smith"`
 - `git config --global user.email jsmith@seas.upenn.edu`
- You only need to do this once
- If you want to use a different name/email address for a particular project, you can change it for just that project
 - `cd` to the project directory
 - Use the above commands, but leave out the `--global`

Create and fill a repository

1. `cd` to the project directory you want to use
2. Type in `git init`
 - This creates the repository (a directory named `.git`)
 - You seldom (if ever) need to look inside this directory
3. Type in `git add .`
 - The period at the end is part of this command!
 - Period means “this directory”
 - This adds all your current files to the repository
4. Type in `git commit -m "Initial commit"`
 - You can use a different commit message, if you like

Clone a repository from elsewhere

- `git clone URL`
- `git clone URL mypath`
 - These make an exact copy of the repository at the given URL
- `git clone git://github.com/rest_of_path/file.git`
 - Github is the most popular (free) public repository
- All repositories are equal
 - But you can treat some particular repository (such as one on Github) as the “master” directory
- Typically, each team member works in his/her own repository, and “merges” with other repositories as appropriate

The repository

- Your top-level **working directory** contains everything about your project
 - The working directory probably contains many subdirectories—source code, binaries, documentation, data files, etc.
 - One of these subdirectories, named `.git`, is your repository
- At any time, you can take a “snapshot” of everything (or selected things) in your project directory, and put it in your repository
 - This “snapshot” is called a **commit object**
 - The commit object contains (1) a set of files, (2) references to the “parents” of the commit object, and (3) a unique “SHA1” name
 - Commit objects do *not* require huge amounts of memory
- You can work as much as you like in your working directory, but the repository isn’t updated until you `commit` something

init and the .git repository

- When you said `git init` in your project directory, or when you cloned an existing project, you created a repository
 - The repository is a subdirectory named `.git` containing various files
 - The dot indicates a “hidden” directory
 - You do *not* work directly with the contents of that directory; various git commands do that for you
 - You *do* need a basic understanding of what is in the repository

Making commits

- You do your work in your project directory, as usual
- If you create new files and/or folders, they are *not tracked* by Git unless you ask it to do so
 - `git add newFile1 newFolder1 newFolder2 newFile2`
- Committing makes a “snapshot” of everything being tracked into your repository
 - A message telling what you have done is required
 - `git commit -m “Uncrevulated the conundrum bar”`
 - `git commit`
 - This version opens an editor for you to enter the message
 - To finish, save and quit the editor
- Format of the commit message
 - One line containing the complete summary
 - If more than one line, the second line must be blank

Commits and graphs

- A **commit** is when you tell git that a change (or addition) you have made is ready to be included in the project
- When you commit your change to git, it creates a **commit object**
 - A commit object represents the complete state of the project, including all the files in the project
 - The *very first* commit object has no “parents”
 - Usually, you take some commit object, make some changes, and create a new commit object; the original commit object is the parent of the new commit object
 - Hence, most commit objects have a single parent
 - You can also **merge** two commit objects to form a new one
 - The new commit object has two parents
- Hence, commit objects form a **directed graph**
 - Git is all about using and manipulating this graph

Working with your own repository

- A **head** is a reference to a commit object
- The “current head” is called **HEAD** (all caps)
- Usually, you will take **HEAD** (the current commit object), make some changes to it, and commit the changes, creating a new current commit object
 - This results in a linear graph: $A \rightarrow B \rightarrow C \rightarrow \dots \rightarrow \text{HEAD}$
- You can also take any previous commit object, make changes to it, and commit those changes
 - This creates a branch in the graph of commit objects
- You can merge any previous commit objects
 - This joins branches in the commit graph

Commit messages

- In git, “Commits are cheap.” Do them often.
- When you commit, you must provide a one-line message stating what you have done
 - Terrible message: “Fixed a bunch of things”
 - Better message: “Corrected the calculation of median scores”
- Commit messages can be very helpful, to yourself as well as to your team members
- You can’t say much in one line, so commit often

Choose an editor

- When you “commit,” git will require you to type in a commit message
- For longer commit messages, you will use an editor
- The default editor is probably `vim`
- To change the default editor:
 - `git config --global core.editor /path/to/editor`
- You may also want to turn on colors:
 - `git config --global color.ui auto`

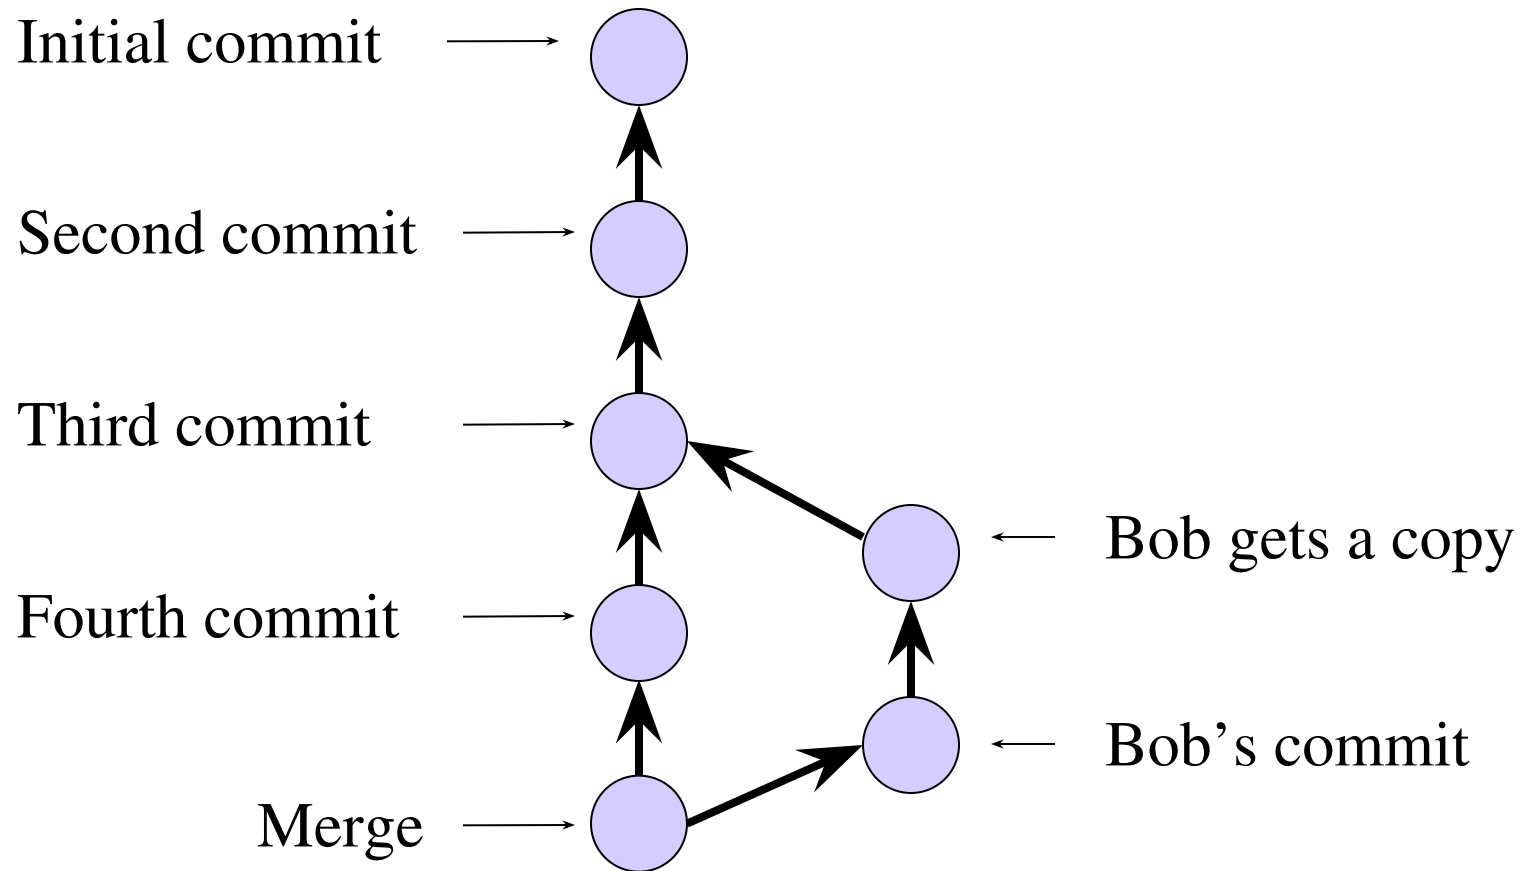

Working with others

- All repositories are equal, but it is convenient to have one central repository in the cloud
- Here's what you normally do:
 - Download the current HEAD from the central repository
 - Make your changes
 - Commit your changes to your local repository
 - Check to make sure someone else on your team hasn't updated the central repository since you got it
 - Upload your changes to the central repository
- If the central repository *has* changed since you got it:
 - It is *your* responsibility to **merge your two versions**
 - This is a strong incentive to commit and upload often!
 - Git can often do this for you, if there aren't incompatible changes

Typical workflow

- `git pull remote_repository`
 - Get changes from a remote repository and merge them into your own repository
- `git status`
 - See what Git thinks is going on
 - Use this frequently!
- Work on your files (remember to add any new ones)
- `git commit -m "What I did"`
- `git push`

Multiple versions

Keeping it simple

- If you:
 - Make sure you are current with the central repository
 - Make some improvements to your code
 - Update the central repository before anyone else does
- Then you don't have to worry about resolving conflicts or working with multiple branches
 - All the complexity in git comes from dealing with these
- Therefore:
 - Make sure you are up-to-date before starting to work
 - Commit and update the central repository frequently
- If you need help: <https://help.github.com/>
